Abstract: **The rapid expansion of remote work is transforming the social structure of organizations by reshaping relationships between workers and their employers. Although remote work offers greater flexibility and productivity, digital surveillance raises concerns about employee autonomy, privacy, and workplace trust. Drawing upon Transaction Cost Economics, Principal-Agent Theory, and the Human Capital Perspective, this paper assesses the balance between workplace flexibility and organizational control. It argues that digital monitoring of employees' activities may undermine trust, motivation, and creativity, whereas outcome-based evaluation of employees greatly motivates them. Furthermore, it argues that trust, as productive social capital, strengthens organizational commitment, collaboration, and human capital development. Finally, the paper proposes a hybrid work model that balances employee autonomy with accountability. Productive remote work requires a shift from intrusive surveillance to trust-based management and performance evaluation, fostering an efficient and human-centered workplace.**

Keywords: **Remote Work, Social Structure, Trust, Autonomy, Digital Surveillance, Human Capital.**

I. INTRODUCTION

In the digital era, the rapid expansion of remote work is reshaping organizational social structures by redefining how workers and their employers negotiate trust, autonomy, and control. While remote workers greatly benefit from reduced commuting time and improved work-life balance, they dislike being monitored for their screen time and online activities. Therefore, firms face a trade-off between offering the opportunity to work remotely and ensuring employees' productivity and efficiency. Drawing upon *Transaction Cost Economics, Principal-Agent Theory,* and *the Human Capital Perspective*, this essay argues that firms should accommodate flexibility in remote work, replace intrusive monitoring with outcome-based evaluation as an effective incentive mechanism, implement trust-enhancing management systems for sustainable human capital, and adopt a hybrid work model as an optimal contract. Such hybrid arrangements align employees' incentives with firms' objectives while preserving employee autonomy and motivation in a principal-agent relationship for remote work.

II. THE SOCIAL ECOLOGY OF WORKPLACE FLEXIBILITY

Remote work reshapes social and economic structures by optimizing workers' productivity. Productivity is the ratio of output to input. It will be maximized by producing more output with less input. In remote work, commuting time and the opportunity cost of time are minimized, the match between labor force supply and demand is optimized, and hiring costs are reduced with high retention. According to Transaction Cost Economics [1], the shift toward remote work has greatly reduced costs in the economic exchange between workers and employers. This is in line with the tenet of Transaction Cost Economics, which focuses on bargaining costs (time reallocation), information search costs (improved match quality), and compliance costs (high retention). The lower input and high efficiency lead to enhanced productivity.

Time reallocation. Remote work changes the opportunity cost of time and lowers bargaining costs between the parties in an economic exchange. People spend time on their work instead of commuting between work and home. Such reallocation of time leads to high productivity and efficient use of time.

Increased match quality. Remote options broaden the labor supply by enabling workers with diverse skills and increasing the quality of the match between jobs and skills. Without geographic constraints, there are more opportunities to fit into a job position with the right people, at lower search costs, which, in the long run, will greatly enhance productivity.

High retention. Due to reduced attrition and increased flexibility in remote work, employee turnover is much lower. This will decrease the costs of ensuring contract compliance in the economic exchange. Higher retention reduces hiring and training costs; therefore, long-run productivity will improve with less input.

As shown in Figure 1, increases in the number of remote workers improve total factor productivity, a measure of efficiency.

III. THE MECHANICS OF DIGITAL SURVEILLANCE

While the flexibility of remote work can increase productivity and efficiency, there are potential negative effects of monitoring employees' activities and online behavior. Employee monitoring is changing the balance of power, trust, and autonomy between employers and workers. Based on principal-agent theory, heavy monitoring increases agents' work effort only through a disciplining effect when surveillance transaction costs are low. In the economic exchange between principals and agents, agents (employees) are required to perform tasks in the interests of principals (firms), constant monitoring can enhance work effort by preventing shirking. With tight monitoring, employees may perceive distrust and a lack of confidence, undermining the psychological contract embedded in the principal-agent relationship between firms and employees. Such a crowding-out effect results in reduced work effort and productivity [2]. When workers are evaluated based on observable activities such as screen time and keystrokes, they may appear busy rather than focus on value creation for the firm, which can encourage counterproductive behavior and reduce work efficiency. Goodhart's Law holds that when a measure is used to reward employees' performance, they are provided with an incentive to manipulate the measure in order to get the reward. With constant surveillance of online activities, employees become less willing to take initiative due to a lack of privacy and autonomy, which greatly curtails creativity and reduces productivity, thereby jeopardizing a firm's core competence.

However, with the increasing demand for remote workers in the past decade, as shown in Figure 2, it is imperative for firms to develop an effective mechanism to provide flexibility in remote work with a disciplining effect and, at the same time, show their trust and confidence in employees to reduce the crowding-out effect [3] without relying on intrusive surveillance.

IV. FROM BEHAVIOR CONTROL TO VALUE CREATION: THE SOCIAL STRUCTURE OF EVALUATION

Outcome-based Evaluation. Firms should focus on the performance outcomes rather than monitoring online hours and activities. Rewards and recognition directly linked to productivity can greatly motivate employees to use their time efficiently, encourage them to put great effort into their work, and maximize value creation. This motivation effect is reflected in the wage divergence between remote and on-site workers. Remote workers earned a wage premium compared to on-site workers [4]. As shown in Figure 3, wage divergence between remote and non-remote work increases for both men and women.

Figure 3. Diverging Wage Gap between Remote and On-Site Workers

Principal-agent theory explains the conflict between employee flexibility and firm surveillance. Firms (principals) cannot learn the effort of employees (agents) by monitoring their online activities, which only reduces their motivation, commitment, and creativity. In principal-agent theory, principals assign work to agents, who conduct it on the principal's behalf. When both parties have different interests, conflict arises. What a principal needs to do is develop an optimal control mechanism that motivates agents to work in the principal's interests. The relationship between a firm and its remote workers has a principal-agent structure; the optimal control strategy [5] can be outcome control through performance-based evaluation rather than behavior control through monitoring remote workers' online behavior. Such outcome control resolves

the conflict in the principal-agent relationship while preserving autonomy and fostering agents' commitment and accountability.

Trust as Productive Capital. In a principal-agent relationship, there is a psychological contract centered on trust and shared value between the parties. Monitoring undermines trust and confidence. An effective trust-enhancing management system shifts the dynamic from monitoring to effective communication and mutual collaboration. When firms punish defecting behaviors such as shirking, they are willing to invest in cooperative tendencies, thus fostering endogenous trust [6]. According to the Human Capital Perspective [7], a firm's performance is largely driven by its human capital. Trust leads to enhanced organizational commitment, employee retention, engagement, and collaboration. It also creates an organizational culture for knowledge sharing, continuous learning, and skill development. Therefore, employees are motivated to improve their skills and expertise to align with firms' objectives. In an empirical study, [8] found that trust has a positive and significant effect on the development of human capital. Trust functions as an intangible productive capital that reduces transaction costs and fosters the accumulation and cultivation of human capital. With trust and long-term commitment, firms are willing to invest in developing human capital by providing career development opportunities and supportive work environments to increase productivity and value creation, rather than relying on monitoring devices, which may undermine the human capital firms seek to cultivate.

A Hybrid Work Model as the Optimal Contract. To develop a balanced approach to accommodating remote work and building employees' accountability, firms should adopt a hybrid work model that includes both remote and on-site work. For example, allowing employees to work from home one day per week to gain flexibility and efficiency while maintaining effective collaboration, organizational culture, and supervision on office days. With a hybrid work model, firms can provide employees with the opportunity to work remotely and conduct performance measurements based on outcomes and productivity. In this way, employees benefit from the flexibility of remote work, while firms maintain a high level of accountability through outcome-based reward systems. The hybrid work model can minimize surveillance costs while optimizing human capital and maximizing accountability and productivity. In a principal-agent structure, with the hybrid mechanism, firms can take advantage of the disciplining effect through monitoring and maintain the psychological contract by building trust to offset the crowding-out effect.

In summary, the future of remote work depends on building a social structure that balances flexibility and accountability through trust rather than intrusive surveillance. Remote work can be a catalyst for human capital production and productivity growth when outcome and behavioral control strategies are optimized through a hybrid model, in which firms ensure the productive use of working hours and focus on performance outcomes without resorting to intense surveillance. Aligning incentives effectively and creating trust can simultaneously provide flexibility employees value and accountability and productivity firms require.
